**Abstract** A 12-residue peptide (R<sup>1</sup>G<sup>2</sup>T<sup>3</sup>F<sup>4</sup>W<sup>5</sup>V<sup>6</sup>d-P<sup>7</sup>S<sup>8</sup>V<sup>9</sup>N<sup>10</sup>Y<sup>11</sup>F<sup>12</sup>,  $\beta$ 2) with cross-strand amino acid pairs V<sup>6</sup>V<sup>9</sup>, F<sup>4</sup>Y<sup>11</sup> and Y<sup>3</sup>F<sup>12</sup>, predicted to form  $\beta$ -hairpin, was designed and synthesized by Fmoc/Bu<sup>t</sup> strategy. The circular dichroism spectrum of  $\beta$ 2 in PBS buffer shows a maximum at about 202 nm and a minimum at about 217.5 nm, a typical  $\beta$ -hairpin characteristics that have been postulated as the common contribution from a  $\beta$ -turn mixed with a  $\beta$ -sheet. The FTIR experiments confirmed the secondary structural contents of  $\beta$ 2.

**Keywords:** *de novo* design,  $\beta$ -hairpin,  $\beta$ -turn,  $\beta$ -sheet, Cross-strand amino acid pairs, CD, FTIR

Designing peptide with a predictable folding pattern is of great interest at present, which is helpful to discover the forces determining protein folds and stability<sup>[1-2]</sup>. Helices and  $\beta$ -sheet, being suggested as the nucleation sites of protein folding<sup>[3-4]</sup>, are the major elements in native proteins. Because  $\beta$ -sheet tends to aggregate in aqueous solution, it is difficult to discover the folding disciplinary of  $\beta$ -structure. A  $\beta$ -hairpin, constructed by two segments of antiparallel  $\beta$ -strand connected with a  $\beta$ -turn, was a simple template to study the interaction between antiparallel sheets<sup>[2]</sup>. Several  $\beta$ -hairpin sequences from the fragments of native protein or modified ones were reported in recent years<sup>[3,5-9]</sup>, and most of them were stabilized using organic reagents, such as TFE and alcohol. According to the reports, factors, like  $\beta$ -turn type, long-range interaction between sheets, hydrophobic interaction are important in  $\beta$ -hairpin formation. Obviously, the solvent effects also play important roles in  $\beta$ -hairpin stability, which were dis-

cussed in most of recent reports<sup>[3,7-12]</sup>. Here we report a designed 12-residue  $\beta$ -hairpin whose strands were constructed with cross-strand amino acid pairs F<sup>4</sup>Y<sup>11</sup> and V<sup>6</sup>V<sup>9</sup> to strengthen the side chain interactions across strands. The peptide was synthesized by solid phase peptide synthesis strategy using Fmoc chemistry, purified by high performance liquid chromatography (HPLC), and investigated by circular dichroism (CD) and FTIR spectra, respectively.

## 1 Peptide design

A 12-residue peptide with  $\beta$ -hairpin forming propensity was designed (Fig. 1). The strong type II'  $\beta$ -turn d-ProSer, providing a good orientation of the extended structure<sup>[10-13]</sup>, was selected to enhance the structural stability. The best  $\beta$ -sheet forming residues Val, Trp, Phe and Tyr were used to construct the two strands. To enhance the interactions between the two strands, we selected the most favorable  $\beta$ -sheet forming amino acid pairs FY and VV to construct the

Fig. 1 Molecular model of  $\beta 2$

side chain interactions across strand<sup>[14]</sup>. In order to increase the peptide solubility in water and destroy the aggregation, the amino acid Arg with a positive charge in neutral or acidic solution was spaced by Gly to the *N*-terminal of the peptide<sup>[11]</sup>.

## 2 Materials and methods

### 2.1 Peptide synthesis and purification

The peptides were synthesized on Wang resin (substitution  $0.8 \text{ mmol} \cdot \text{g}^{-1}$ , ACT product, USA) by Fmoc/Bu<sup>t</sup> strategy<sup>[15]</sup>. The first amino acid Phe was loaded to the resin by preformed symmetrical anhydride method and catalyzed by *N,N*-dimethylaminopyridine. 2-(1*H*-benzotriazol-1-yl)-1, 1, 3, 3-tetramethyl uranium hexafluorophosphate (HBTU) and 1-hydroxybenzotriazole (HOBT) were selected as the coupling reagents. The protected amino acids are FmocLeu, Fmoc(*d*-)Pro, FmocVal, FmocGly, FmocPhe, FmocTrp, FmocAsn, FmocAsp (Bu<sup>t</sup>), FmocTyr (Bu<sup>t</sup>), FmocArg(Mtr) and FmocThr (Bu<sup>t</sup>) (ACT products, USA). The peptide resin was cleaved by K reagent, and the crude products were purified by RP-HPLC (Gilson Inc. France, zorbax C<sub>18</sub> column,  $9.4 \text{ mm} \times$

$250 \text{ mm}$ ). The peptides were confirmed by RP-HPLC (zorbax C<sub>18</sub> column,  $4.6 \text{ mm} \times 250 \text{ mm}$ ) and MALDI-TOF mass spectra.

### 2.2 CD spectroscopy

The CD spectra were recorded on Jobin Yvon-Spex CD6 at  $20 \text{ }^\circ\text{C}$ . Samples were prepared using PBS buffer at about  $0.68 \text{ mmol} \cdot \text{L}^{-1}$  with pH 7.04. Scans were obtained in a range between 184 nm and 260 nm by taking points every 0.5 nm, with an integration time of 1 s and a 2 nm bandwidth. Cells with path length of 0.1 mm were used.

### 2.3 Fourier transferred infrared spectroscopy

The IR spectra were obtained on Bio-Rad FTS 165 FTIR spectrometer equipped with a DTGS detector at room temperature. The solution of  $\beta 2$  was prepared in D<sub>2</sub>O at  $6.8 \text{ mmol} \cdot \text{L}^{-1}$  and the path length was  $25 \text{ } \mu\text{m}$  for the measurement. The spectrum was obtained by averaging 400 scans with a nominal resolution of  $4 \text{ cm}^{-1}$ , and then Fourier transforming with a triangular apodization function. Curve fitting was performed with the Bio-Rad Win-IR CURVEFIT. AB program. Trifluoroacetic acid used both in peptide synthesis and in the HPLC mobile phase was removed after several lyophilization-solubilization cycles in  $10 \text{ mmol} \cdot \text{L}^{-1}$  HCl solution.

## 3 Results and discussion

In order to destroy the peptide aggregation and increase the solubility in water, the residue Arg was

Fig. 2 The CD spectrum of  $\beta 2$  in PBS buffer pH 7.04,  $0.68 \text{ mmol} \cdot \text{L}^{-1}$  at  $20 \text{ }^\circ\text{C}$

Fig. 3 Decomposition of the amide I band of  $\beta 2$  in PBS buffer (D<sub>2</sub>O) at  $20 \text{ }^\circ\text{C}$

Table 1 The secondary structural contents, percentage area and assignment of  $\beta 2$ 

Band position (cm <sup>-1</sup> )	Area (%)	Assignment
1684	5.3	$\beta$ -turn
1676	11.7	$\beta$ -sheet
1663	36.7	$\beta$ -turn
1650	12.2	helix
1636	30.9	$\beta$ -sheet
1613	3.2	side chain

linked on the *N*-terminal of the peptide whose positive charge repulsion in acidic or neutral condition will prevent aggregation<sup>[11]</sup>. As a result,  $\beta 2$  exhibited excellent solubility in water, and the CD spectra of  $\beta 2$  did not show concentration dependence at a range 0.68 mmol · L<sup>-1</sup> ~ 68  $\mu$ mol · L<sup>-1</sup> in PBS (data not shown).

The CD curve of  $\beta 2$  presented in Fig. 2, exhibits a maximum near 202 nm and minimum near 217.5 nm, the typical characteristics of  $\beta$ -hairpin, and which have been postulated as the mixed contribution from  $\beta$ -turn to  $\beta$ -sheet<sup>[16]</sup>. The CD curve of the  $\beta$ -hairpin peptide BH8 in 30% TFE shows similar characteristics of a maximum at 202 nm and a similar minimum at 216 nm<sup>[11]</sup>, which supports our postulation.

Obviously,  $\beta$ -turn plays important roles in designed  $\beta$ -hairpin formation and stability. It determines not only the turn conformation, but also the pattern of interstrand residue pairing and the backbone hydrogen bonding register between the  $\beta$ -strands<sup>[10, 13]</sup>. We reported that the turn sequence *d*-ProSer behaves well than GlySer<sup>[17]</sup>, and Haque and his colleagues<sup>[11]</sup> also reported that the  $\beta$ -hairpin could be stabilized using the enforced turns like *d*-Pro(*d*-)Ala, *d*-ProGly or *d*-ProAla. They also pointed out that the conformational proclivity of the backbone is at least as important as hydrogen bonding and hydrophobic interactions in stabilizing  $\beta$ -hairpin conformation. To test the roles of the turn sequence played in the  $\beta$ -hairpin formation of  $\beta 2$ , we synthesized a B1 mutant (R<sup>1</sup>G<sup>2</sup>T<sup>3</sup>F<sup>4</sup>Y<sup>5</sup>V<sup>6</sup>G<sup>7</sup>D<sup>8</sup>V<sup>9</sup>N<sup>10</sup>Y<sup>11</sup>F<sup>12</sup>), characterized its structure by CD spectroscopy. The CD curve of a negative near 193 nm

and a broad weak negative between 205 nm and 218 nm imply that the  $\beta 2$  mutant lost  $\beta$ -hairpin conformation (data not shown) and confirmed the  $\beta$ -turn contribution to  $\beta$ -hairpin formation of  $\beta 2$ .

The conformation of  $\beta 2$  in PBS (D<sub>2</sub>O) was also investigated by FTIR, and Fig. 3 shows the decomposed band together with the deconvoluted amide I infrared spectra. Six bands located at 1683, 1674, 1662, 1646, 1633 and 1612 cm<sup>-1</sup> were observed and the bond position, percentage area, and assignment of the components are shown in Table 1.

Theoretical calculations of antiparallel  $\beta$ -sheet predict a high frequency infrared component near 1676 cm<sup>-1</sup><sup>[18]</sup>, and many previous studies took this peak as diagnostic for antiparallel  $\beta$ -structures<sup>[19-20]</sup>. So we assigned the maximum band at 1676 cm<sup>-1</sup> to the high frequency component of  $\beta$ -sheet. Consequently, the band at 1636 cm<sup>-1</sup> is assigned to the low frequency component of  $\beta$ -sheet<sup>[21]</sup>. Two bands located at 1684 and 1663 cm<sup>-1</sup> are assigned to  $\beta$ -turn<sup>[22]</sup>. Unfortunately, it is not clear why one type of turn gives rise to more than one band, but this assignment is consistent with the studies of  $\beta$ -turn structure and  $\beta$ -hairpin structure<sup>[18-22]</sup>. The band at 1650 cm<sup>-1</sup> is always assigned to helix in D<sub>2</sub>O<sup>[19, 24-26]</sup>. It is clear that the band at 1613 cm<sup>-1</sup> is considered as from absorbency of aromatic side chains, like Tyr, Trp and Phe<sup>[27-29]</sup>.

## 4 Conclusion

CD and FTIR experiments revealed that  $\beta 2$  forms  $\beta$ -hairpin structure in solution. The  $\beta$ -turn is key factor of the  $\beta$ -hairpin formation, and it determines

not only the turn conformation but also the orientation of the strands and the interactions between the two strands of  $\beta$ -hairpin of  $\beta 2$ . Usually, it spends much effort to design a peptide sequence with special folds in *de novo* protein design due to the complex interactions and the unpredictable factors of protein. The success of designing the simple template of  $\beta$ -hairpin by cross-strand amino acid pair strategy would supply an economic way to design  $\beta$ -sheet related structures.
